

PROJECT 2

Restaurant Growth Analysis

SkyCity Auckland Restaurants & Bars

A business analytics project focused on restaurant growth potential, profitability, channel economics and strategic classification.

Metric	Value
Restaurant records	1,696
Source fields	30
Total revenue	\$77.74M
Total net profit	\$7.87M
Portfolio margin	10.1%

Prepared for Business Analyst internship project submission.

1. Business Objective & Dataset

Objective: identify growth opportunities, understand channel profitability, classify restaurants by growth potential, and translate findings into practical actions.

Dataset coverage

The dataset contains restaurant-level information across cuisine type, restaurant segment, Auckland subregion, growth factor, average order value, monthly orders, channel revenue, cost rates, delivery economics and channel-level net profit. No missing values were found.

Data validation

MonthlyOrders reconciles exactly with the sum of in-store, Uber Eats, DoorDash and self-delivery orders for every restaurant. This provides a clean base for channel analysis.

Dimension	Categories / count
Cuisine	8 cuisine types
Segment	4 formats: QSR, Cafe, Full-service, Ghost Kitchen
Subregion	4: CBD, North Shore, South Auckland, West Auckland
Channels	In-store, Uber Eats, DoorDash, Self-delivery

2. Key Findings

Channel economics

In-store and self-delivery show much stronger unit economics than the third-party delivery channels. In the dataset, Uber Eats has approximately a 0.8% aggregate net margin and DoorDash approximately 0.9%, versus about 26.8% for in-store and 22.9% for self-delivery.

Segment economics

Cafe and QSR generate substantial aggregate profit, while Ghost Kitchen shows the highest segment-level margin. Full-service restaurants are loss-making in aggregate, making the format a key turnaround area.

Geographic signal

South Auckland has the highest growth factor in the dataset (1.05), followed by West Auckland (1.04), North Shore (1.03) and CBD (0.99).

Portfolio economics

Across all channels, the dataset represents approximately 2.02M monthly orders, \$77.74M in revenue and \$7.87M in net profit, producing an overall margin of 10.1%.

3. Growth Potential Model

A Growth Potential Index (GPI) was created as a transparent prioritization framework. Four normalized features are weighted: Growth Factor 30%, Profit Margin 35%, Monthly Orders 20% and AOV 15%. Each feature is scaled to 0–100 before weighting.

Classification thresholds: Low below 45.8; Medium from 45.8 to 63.5; High above 63.5.

Class	Restaurants	Revenue	Net Profit	Margin
High	509	\$28.04M	\$4.93M	17.6%
Medium	678	\$29.69M	\$1.99M	6.7%
Low	509	\$20.00M	\$0.94M	4.7%

Important: the GPI is a prioritization framework based on the available dataset; it is not a guarantee of future growth.

4. Recommendations & Deployment Plan

Recommended actions

- Protect profitable channels by strengthening in-store and self-delivery economics.
- Review third-party delivery pricing, commissions, bundles and minimum order values where unit economics are weak.
- Prioritize high-potential restaurants in South and West Auckland for growth experiments.
- Investigate full-service restaurants for cost, pricing and format redesign opportunities.
- Use restaurant-level classification to target interventions rather than applying one strategy to the entire portfolio.

Planned technical deliverables

GitHub repository containing the Streamlit application, requirements, README and analysis dataset; deployed Streamlit dashboard; 5-page project documentation; presentation deck; and a short project feedback video.

Dashboard filters

Subregion • Segment • Cuisine • Growth Class • Sales Channel, with KPI cards for revenue, orders, net profit, margin and restaurant count.

Final takeaway

The opportunity is not simply to grow sales. The stronger business question is: where can growth be converted into sustainable profit? The analysis provides a restaurant-level framework for making that decision.
